

UTF-8 installations of T_EX

Igor Liferenko

Abstract

In its design T_EX has the concepts of “internal encoding” and “external encoding”. This fact allows T_EX to work with any encoding.

We use Unicode as T_EX’s external encoding. Then we change the necessary parts of T_EX to use UTF-8 as the input/output encoding.

The resulting implementation passes the trip test.

1. Initialization

Note: we use the *web2w* [1] implementation of T_EX, but the ideas described here can be applied to any implementation.

First, we change the data type of characters in text files to `wchar_t` to accommodate Unicode values.

Background: this predefined C type allocates four bytes per character (on most systems). Character constants of this type are written as `L'...'` and string constants as `L"..."`.

(For brevity, in the diffs following, the original code from *web2w*’s `ctex.w` source is preceded with `<` characters, and the new code with `>`. Both are sometimes reformatted for presentation in this article, and for readability we sometimes leave a blank line between the pieces. The actual implementation uses the file `utex.patch` [2].)

```
< @d text_char pascal_char
> @d text_char wchar_t
```

Use values from the basic multilingual plane (BMP) of Unicode.

```
< @d last_text_char 255
> @d last_text_char 65535
```

Then we change the size of the *xord* array [3] to 2¹⁶ bytes.

```
< ASCII_code xord[256];
> ASCII_code xord[65536];
```

Elements in the *xchr* array [3] are overridden using the file `mapping.w`.

```
@i mapping.w
```

This file specifies the character(s) required for a particular installation of T_EX, for example:

```
xchr[0xf1] = L'ë';
```

A complete example of `mapping.w` is here:

<https://github.com/igor-liferenko/cweb>

Let’s make `pascal_char` and `text_char` the same type by analogy with `tex.web` (see §19 in [3]).

```
< pascal_char TEX_format_default[]=" TeX...
> wchar_t TEX_format_default[]=L" TeXfor...
```

```
< pascal_char months[]=" JANFEBMARAPRMAY...
> wchar_t months[]=L" JANFEBMARAPRMAYJUN...
```

The exception is *name_of_file*.

```
< pascal_char name_of_file0
< [file_name_size+1] = {0},
< *const name_of_file = name_of_file0-1;
< /* on some systems this may be a
< \&{record} variable */
```

```
> char name_of_file0
> [file_name_size+1] = {0},
> *const name_of_file = name_of_file0-1;
> /* UTF-8 string */
```

It remains to set the `LC_CTYPE` locale category, on which depends the behavior of the C library functions used below

```
setlocale(LC_CTYPE, "C.UTF-8");
```

and to add the necessary headers.

```
#include <wchar.h>
#include <locale.h>
```

2. Input

For automatic conversion from UTF-8 to Unicode, text files (including the terminal) must be read with the C library function *fgetwc* [4].

In `ctex.w` the macro *get* is used for reading text files, as well as font metric and format files.

Text files are read in the functions *a_open.in* and *input.ln*. In *a_open.in* we replace the macro *reset* with its expansion and then in both functions we change `get((*f))` to `(*f).d=fgetwc((*f).f)`

3. Output

Printed strings can be specified directly in UTF-8. And as they are already in ASCII (which is part of UTF-8) we need no special treatment for them, except that `%c` is changed to `%lc`.

```
< wlog("%c",months[k]);
> wlog("%lc",months[k]);
```

```
< wterm("%c",xchr[s]);
> wterm("%lc",xchr[s]);
```

```
< wlog("%c",xchr[s]);
> wlog("%lc",xchr[s]);
```

```
< write(write_file[selector],"%c",xchr[s]);
> write(write_file[selector],"%lc",xchr[s]);
```

4. The file name buffer

The name of the file to be opened, which is stored in the *name_of_file* buffer, must be encoded in UTF-8. Therefore, each character passed to *append_to_name*, before being added to *name_of_file*, must be converted to UTF-8. This is done using the C library function *wctomb* [4].

In the *append_to_name* macro, the variable *k* is used as the index into the *name_of_file* buffer where the last byte was stored. Originally, *k* was always increased and provisions were made that characters will not be written beyond the end of buffer (which has the index *file_name_size*); *name_length* was then set to the minimal value between *k* and *file_name_size*.

We cannot do the same in our implementation, because we may reach the end of the buffer in the midst of a multibyte character. Instead, if the next multibyte character does not fit into the buffer, we prevent *k* from being increased by negating its value:

```
< @d append_to_name(X) { c=X;incr(k);
<   if (k <= file_name_size)
<     name_of_file[k]=xchr[c]; }

> @d append_to_name(X) { c=X;
>   if (k >= 0) { /* try to append? */
>     char mb[MB_CUR_MAX];
>     int len = wctomb(mb, xchr[c]);
>     if (k+len <= file_name_size)
>       for (int i = 0; i < len; i++)
>         name_of_file[++k] = mb[i];
>     else
>       k = -k; /* freeze k */ } }
```

In *pack_file_name* and *pack_buffered_name* (the functions that call *append_to_name*), we have to “un-freeze” its value if it was “frozen”.

```
if (k < 0) k = -k;
```

In *make_name_string*, each (multibyte) character from *name_of_file* must be converted from UTF-8 to Unicode, before being converted to T_EX’s internal encoding. This is done using the C library function *mbtowc* [4].

```
< append_char(xord[name_of_file[k]]);

> { wchar_t wc;
>   k += mbtowc(&wc, name_of_file+k,
>             MB_CUR_MAX) - 1;
>   append_char(xord[wc]); }
```

In the code checking *format_default_length* for consistency, we use the C library function *wcstombs* [4] to count the number of bytes in the UTF-8 representation of *TEX_format_default*.

```
< if (format_default_length >
<     file_name_size)

> if (wcstombs(NULL,
>     TEX_format_default+1,0) >
>     file_name_size)
```

In the function *pack_buffered_name*, the code that drops excess characters assumes that each character is one byte:

```
if (n+b-a+1+format_ext_length >
    file_name_size)
    b=a+file_name_size-n-1-format_ext_length;
```

But the number of bytes used to represent a character in UTF-8 may be more than one. Therefore, we use an equivalent method to drop excess characters, the one which will work with multibyte characters: After appending the contents of *buffer[a .. b]* to *name_of_file*, we roll back in it character by character until the format extension fits in it. We use the C library function *mblen* [4] to determine the start of the next (multibyte) character to be discarded.

```
while (k+wcstombs(NULL,TEX_format_default+
    format_default_length-
    format_ext_length+1,0) >
    file_name_size) {
    k--;
    while (mblen(name_of_file+k+1,MB_CUR_MAX)
        ==-1)
        k--;
}
```
